- Quaternion Frame Evolution
- Quaternion Curve and Surface Optimization

IV: Clifford Algebras

- Clifford Algebras: Generalize quaternion structure to N-dimensions
- Reflections and Rotations: New ways of looking at rotations
- Pin(N), Spin(N), O(N), and SO(N)

Visualizing Quaternions

Part I: Fundamentals of Quaternions

Andrew J. Hanson

Indiana University

Part I: OUTLINE

- Motivation
- 2D Frames: Simple example, complex numbers.
- 3D Frames: Rotations and quaternions.

Motivation

- Quaternion methods are now commonplace in graphics.
- Quaternions are very geometric, but we seldom attempt to visualize their properties geometrically.
- That's going to be our job today!

Basic Issues

- Basic fact number 1: Rotation matrices are Coordinate Frame Axes.
- Basic fact number 2: Rotation matrices form groups, which have geometric properties.

Task vs Strategy

Our task: Understand Rotations.

 Rotations don't just act on geometry, rotations are geometry.

 Our strategy: the geometry should help us to visualize the properties of rotations.

Simple Example: 2D Rotations

- 2D rotations ⇒ geometric origin for complex numbers.
- Complex numbers are a special subspace of quaternions.
- Thus 2D rotations introduce us to quaternions and their geometric meaning.

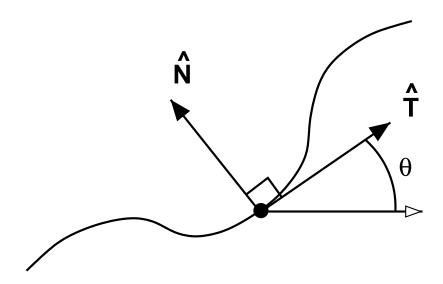

Frames in 2D

The tangent and normal to 2D curve move continuously along the curve:

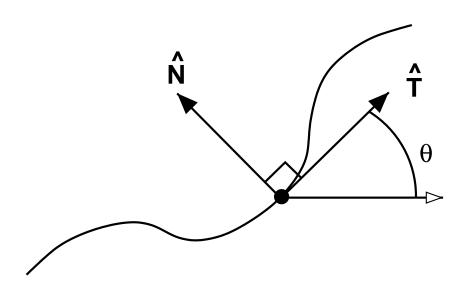

Frames in 2D

The tangent and normal to 2D curve move continuously along the curve:

Frames in 2D

The tangent and normal to 2D curve move continuously along the curve:

Frame Matrix in 2D

This motion is described at each point (or time) by the matrix:

$$R_{2}(\theta) = \begin{bmatrix} \widehat{\mathbf{T}} & \widehat{\mathbf{N}} \end{bmatrix}$$

$$= \begin{bmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{bmatrix}.$$

Another 2D Frame

If we did not know about $\cos^2 \theta + \sin^2 \theta = 1$, we might represent the frame differently, e.g., as:

$$R_2(A,B) = \begin{bmatrix} A & -B \\ B & A \end{bmatrix}.$$

with the constraint $A^2 + B^2 = 1$.

The Belt Trick:

Is There a Problem?

Demonstration: Rotations "want to be doubled" to get

back where you started.

See: Hart, Francis, and Kauffman.

Half-Angle Transform:

A Fix for the Problem?

$$R_2(\theta) = \begin{bmatrix} \cos^2 \frac{\theta}{2} - \sin^2 \frac{\theta}{2} & -2\cos\frac{\theta}{2}\sin\frac{\theta}{2} \\ 2\cos\frac{\theta}{2}\sin\frac{\theta}{2} & \cos^2 \frac{\theta}{2} - \sin^2 \frac{\theta}{2} \end{bmatrix}$$

Half-Angle Transform:

A Fix for the Problem?

Or, with
$$a = \cos(\theta/2)$$
, $b = \sin(\theta/2)$, (i.e., $A = a^2 - b^2$, $B = 2ab$),

we could parameterize as:

$$R_2(a,b) = \begin{bmatrix} a^2 - b^2 & -2ab \\ 2ab & a^2 - b^2 \end{bmatrix}.$$

where orthonormality implies

$$(a^2 + b^2)^2 = 1$$

which reduces back to $a^2 + b^2 = 1$.

Half-Angle Transform:

So the pair (a, b) provides an odd **double-valued** parameterization of the frame:

$$\begin{bmatrix} \hat{\mathbf{T}} & \hat{\mathbf{N}} \end{bmatrix} = \begin{bmatrix} a^2 - b^2 & -2ab \\ 2ab & a^2 - b^2 \end{bmatrix}.$$

where (a, b) is precisely the *same frame* as (-a, -b).

Frame Evolution in 2D

Examine time-evolution of 2D frame (on our way to 3D): First in $\theta(t)$ coordinates:

$$\left[\begin{array}{cc} \widehat{\mathbf{T}} & \widehat{\mathbf{N}} \end{array}\right] = \left[\begin{array}{cc} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{array}\right].$$

Differentiate to find frame equations:

$$\dot{\hat{\mathbf{N}}}(t) = +\kappa \hat{\mathbf{N}}
\dot{\hat{\mathbf{N}}}(t) = -\kappa \hat{\mathbf{T}},$$

where $\kappa(t) = d\theta/dt$ is the curvature.

Frame Evolution in 2D

Rearrange to make a "vector matrix:"

$$\begin{bmatrix} \hat{\mathbf{T}}(t) \\ \hat{\mathbf{N}}(t) \end{bmatrix} = \begin{bmatrix} 0 & +\kappa(t) \\ -\kappa(t) & 0 \end{bmatrix} \begin{bmatrix} \hat{\mathbf{T}}(t) \\ \hat{\mathbf{N}}(t) \end{bmatrix}$$

Frame Evolution in (a, b):

Using the basis $(\widehat{\mathbf{T}}, \widehat{\mathbf{N}})$ we have **Four equations** with **Three constraints** from orthonormality, for **One** true degree of freedom.

Major Simplification occurs in (a, b) coordinates!!

$$\dot{\hat{\mathbf{T}}} = 2 \begin{bmatrix} a\dot{a} - b\dot{b} \\ a\dot{b} + b\dot{a} \end{bmatrix} = 2 \begin{bmatrix} a & -b \\ b & a \end{bmatrix} \begin{bmatrix} \dot{a} \\ \dot{b} \end{bmatrix}$$

Frame Evolution in (a, b):

But this formula for \hat{T} is just $\kappa \hat{N}$, where

$$\kappa \hat{\mathbf{N}} = \kappa \begin{bmatrix} -2ab \\ a^2 - b^2 \end{bmatrix} = \kappa \begin{bmatrix} a & -b \\ b & a \end{bmatrix} \begin{bmatrix} -b \\ a \end{bmatrix}$$

or

$$\kappa \hat{\mathbf{N}} = \kappa \begin{bmatrix} a & -b \\ b & a \end{bmatrix} \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix} \begin{bmatrix} a \\ b \end{bmatrix}$$

2D Quaternion Frames!

Rearranging terms, both $\hat{\mathbf{T}}$ and $\hat{\mathbf{N}}$ eqns reduce to

$$\begin{bmatrix} \dot{a} \\ \dot{b} \end{bmatrix} = \frac{1}{2} \begin{bmatrix} 0 & -\kappa \\ +\kappa & 0 \end{bmatrix} \cdot \begin{bmatrix} a \\ b \end{bmatrix}$$

This is the square root of frame equations.

2D Quaternions . . .

So *one equation* in the two "quaternion" variables (a, b) with the constraint $a^2 + b^2 = 1$ contains both the frame equations

$$\dot{\hat{\mathbf{T}}} = +\kappa \hat{\mathbf{N}}$$

$$\dot{\hat{\mathbf{N}}} = -\kappa \hat{\mathbf{T}}$$

 \Rightarrow this is much better for computer implementation, etc.

Rotation as Complex Multiplication

If we let $(a + ib) = \exp(i\theta/2)$ we see that rotation is complex multiplication!

"Quaternion Frames" in 2D are just complex numbers, with

Evolution Eqns = derivative of $\exp(i\theta/2)!$

Rotation with no matrices!

This is the miracle:

$$a + ib = e^{i\theta/2}$$

represents rotations "more nicely" than the matrices $R(\theta)$.

$$(a' + ib')(a + ib) = e^{i(\theta' + \theta)/2} = A + iB$$

where if we want the matrix, we write:

$$R(\theta')R(\theta) = R(\theta' + \theta) = \begin{bmatrix} A^2 - B^2 & -2AB \\ 2AB & A^2 - B^2 \end{bmatrix}$$

The Algebra of 2D Rotations

The algebra corresponding to 2D rotations is easy: just complex multiplication!!

$$(a',b')*(a,b) \cong (a'+ib')(a+ib)$$

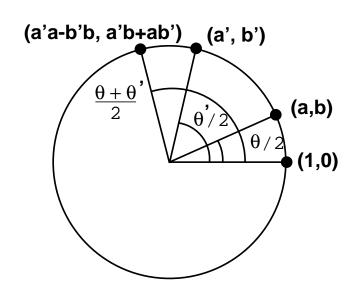

$$= a'a - b'b + i(a'b+ab')$$

$$\cong (a'a - b'b, a'b + ab')$$

$$= (A, B)$$

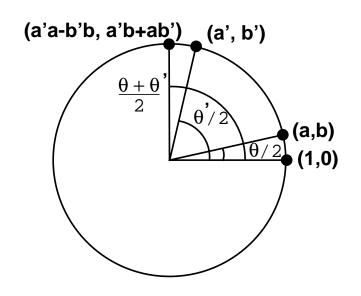

The Geometry of 2D Rotations

(a,b) with $a^2 + b^2 = 1$ is a point on the unit circle, also written S^1 . Rotations are just complex multiplication, and take you around the unit circle like this:

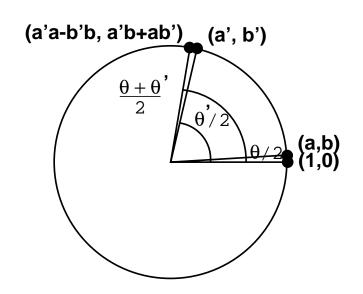

The Geometry of 2D Rotations

(a,b) with $a^2 + b^2 = 1$ is a point on the unit circle, also written S^1 . Rotations are just complex multiplication, and take you around the unit circle like this:

The Geometry of 2D Rotations

(a,b) with $a^2 + b^2 = 1$ is a point on the unit circle, also written S^1 . Rotations are just complex multiplication, and take you around the unit circle like this:

Quaternion Frames

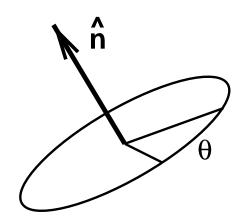

In 3D, repeat our trick: take square root of the frame, but now use *quaternions*:

- Write down the 3D frame.
- Write as double-valued quadratic form.
- Rewrite linearly in the new variables.

The Geometry of 3D Rotations

We begin with a basic fact:

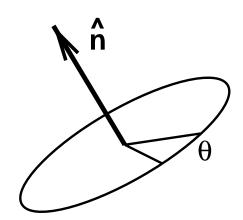

Euler theorem: every 3D frame can be written as a spinning by θ about a fixed axis $\hat{\mathbf{n}}$, the eigenvector of the rotation matrix:

The Geometry of 3D Rotations

We begin with a basic fact:

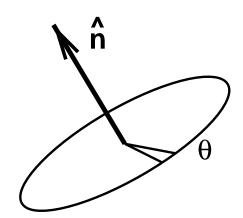

Euler theorem: every 3D frame can be written as a spinning by θ about a fixed axis $\hat{\mathbf{n}}$, the eigenvector of the rotation matrix:

The Geometry of 3D Rotations

We begin with a basic fact:

Euler theorem: every 3D frame can be written as a spinning by θ about a fixed axis $\hat{\mathbf{n}}$, the eigenvector of the rotation matrix:

Quaternion Frames...

Matrix giving 3D rotation by θ about axis $\hat{\mathbf{n}}$:

$$R_3(\theta, \hat{\mathbf{n}}) =$$

$$\begin{bmatrix} c + (n_1)^2 (1-c) & n_1 n_2 (1-c) - s n_3 & n_3 n_1 (1-c) + s n_2 \\ n_1 n_2 (1-c) + s n_3 & c + (n_2)^2 (1-c) & n_3 n_2 (1-c) - s n_1 \\ n_1 n_3 (1-c) - s n_2 & n_2 n_3 (1-c) + s n_1 & c + (n_3)^2 (1-c) \end{bmatrix}$$

where $c = \cos \theta$, $s = \sin \theta$, and $\hat{\mathbf{n}} \cdot \hat{\mathbf{n}} = 1$.

Quaternion Frame Parameters

To find θ and axis $\hat{\mathbf{n}}$, given *any* rotation matrix or frame M, we need two steps:

$$TrM = 1 + 2\cos\theta$$

 \Rightarrow solve for θ .

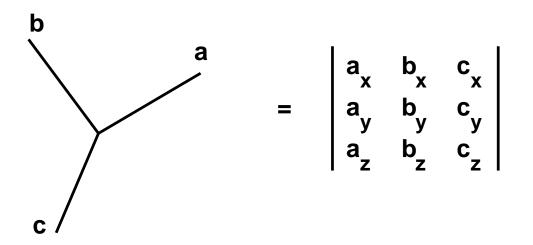

$$M - M^{t} =$$

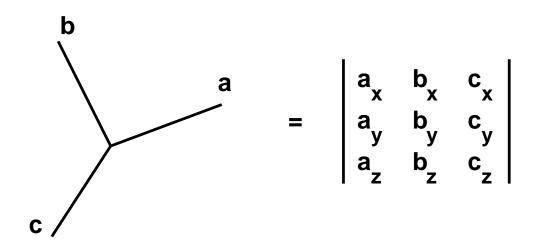

$$\begin{bmatrix} 0 & -2n_{3}\sin\theta & +2n_{2}\sin\theta \\ +2n_{3}\sin\theta & 0 & -2n_{1}\sin\theta \\ -2n_{2}\sin\theta & +2n_{1}\sin\theta & 0 \end{bmatrix}$$

 \Rightarrow solve for $\hat{\mathbf{n}}$ as long as $\theta \neq 0$.

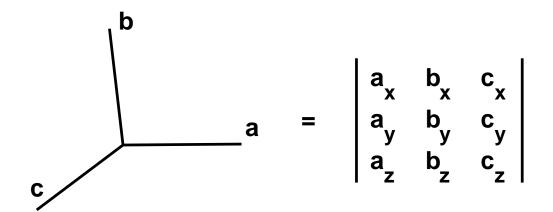

Some set of axes can be chosen as the identity matrix:

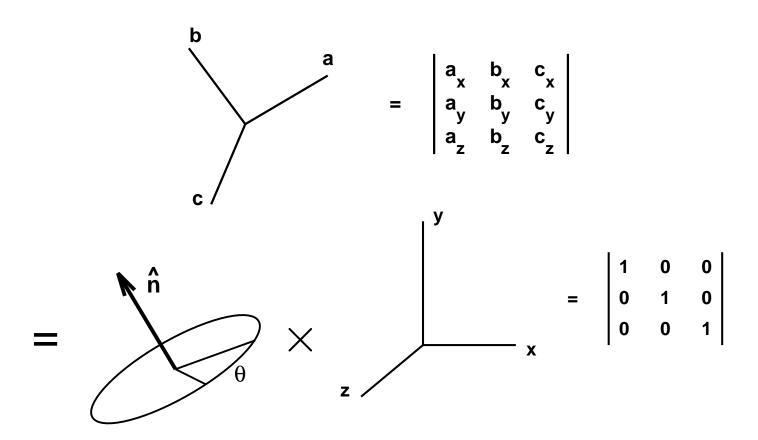

By Euler's theorem, that matrix has an eigenvector \hat{n} , and so is representable as a single rotation about \hat{n} applied to the identity:

Rotations and Quadratic Polynomials

Remember
$$R_2(\theta) = \begin{bmatrix} a^2 - b^2 & -2ab \\ 2ab & a^2 - b^2 \end{bmatrix}$$
?

What if we try a 3 \times 3 matrix R_3 instead of 2 \times 2?

$$\begin{bmatrix} q_0^2 + q_1^2 - q_2^2 - q_3^2 & 2q_1q_2 - 2q_0q_3 & 2q_1q_3 + 2q_0q_2 \\ 2q_1q_2 + 2q_0q_3 & q_0^2 - q_1^2 + q_2^2 - q_3^2 & 2q_2q_3 - 2q_0q_1 \\ 2q_1q_3 - 2q_0q_2 & 2q_2q_3 + 2q_0q_1 & q_0^2 - q_1^2 - q_2^2 + q_3^2 \end{bmatrix}$$

Hint: set $q_1 = q_2 = 0$ or any other $(i \neq j)$ pair to see a familiar sight!

Why does this matrix parameterize a rotation? Because *Columns* of $R_3(q_0, q_1, q_2, q_3)$ are orthogonal:

$$col_i \cdot col_j = 0 \text{ for } i \neq j$$

What is **LENGTH** of 3-vector column?

$$col_i \cdot col_i = (q_0^2 + q_1^2 + q_2^2 + q_3^2)^2$$

So if we require $q_0^2 + q_1^2 + q_2^2 + q_3^2 = 1$, orthonormality is assured and $R_3(q_0, q_1, q_2, q_3)$ is a rotation.

This implies q is a point on 3-sphere in 4D.

NOTE: $q \Rightarrow -q$ gives same $R_3()$.

HOW does $q = (q_0, \mathbf{q})$ represent rotations?

LOOK at

?
$$R_3(\theta, \hat{\mathbf{n}}) \stackrel{?}{=} R_3(q_0, q_1, q_2, q_3)$$

NOTICE: Choosing

$$q(\theta, \hat{\mathbf{n}}) = (\cos \frac{\theta}{2}, \ \hat{\mathbf{n}} \sin \frac{\theta}{2})$$

makes the R_3 equation an *IDENTITY*.

WHAT happens if you do TWO rotations?

EXAMINE the action of two rotations

$$R(q')R(q) = R(Q)$$

EXPRESS in quadratic forms in q and LOOK FOR an analog of complex multiplication:

RESULT: the following multiplication rule q'*q=Q yields **exactly** the correct 3×3 rotation matrix R(Q):

$$\begin{bmatrix} Q_0 = [q' * q]_0 \\ Q_1 = [q' * q]_1 \\ Q_2 = [q' * q]_2 \\ Q_3 = [q' * q]_3 \end{bmatrix} = \begin{bmatrix} q'_0 q_0 - q'_1 q_1 - q'_2 q_2 - q'_3 q_3 \\ q'_0 q_1 + q'_1 q_0 + q'_2 q_3 - q'_3 q_2 \\ q'_0 q_2 + q'_2 q_0 + q'_3 q_1 - q'_1 q_3 \\ q'_0 q_3 + q'_3 q_0 + q'_1 q_2 - q'_2 q_1 \end{bmatrix}$$

This is Quaternion Multiplication.

Algebra of Quaternions = 3D Rotations!

2D rotation matrices are represented

by complex multiplication

3D rotation matrices are represented

by quaternion multiplication

Algebraic 2D/3D Rotations

Therefore in 3D, the 2D complex multiplication

$$(a',b')*(a,b) = (a'a - b'b, a'b + ab')$$

is replaced by 4D quaternion multiplication:

$$q' * q = (q'_0q_0 - q'_1q_1 - q'_2q_2 - q'_3q_3,$$

$$q'_0q_1 + q'_1q_0 + q'_2q_3 - q'_3q_2,$$

$$q'_0q_2 + q'_2q_0 + q'_3q_1 - q'_1q_3,$$

$$q'_0q_3 + q'_3q_0 + q'_1q_2 - q'_2q_1)$$

Algebra of Quaternions . . .

The is easier to remember by dividing it into the *scalar* piece q_0 and the *vector* piece $\vec{\mathbf{q}}$:

$$q' * q = (q'_0 q_0 - \vec{\mathbf{q}'} \cdot \vec{\mathbf{q}},$$
$$q'_0 \vec{\mathbf{q}} + q_0 \vec{\mathbf{q}'} + \vec{\mathbf{q}'} \times \vec{\mathbf{q}})$$

Another miracle: let us generalize the 2D equation

$$a + ib = e^{i\theta/2}$$

How? We set

$$q = (q_0, q_1, q_2, q_3)$$

$$= q_0 + \mathbf{i}q_1 + \mathbf{j}q_2 + \mathbf{k}q_3$$

$$= e^{(\mathbf{I} \cdot \hat{\mathbf{n}}\theta/2)}$$

with $q_0 = \cos(\theta/2)$ and $\vec{\mathbf{q}} = \hat{\mathbf{n}}\sin(\theta/2)$ and $\mathbf{I} = (\mathbf{i}, \mathbf{j}, \mathbf{k})$.

Then if we take $i^2 = j^2 = k^2 = -1$, and i * j = k (cyclic), quaternion multiplication rule is automatic!

 $\Rightarrow q = q_0 + iq_1 + jq_2 + kq_3$ is the standard representation for a *quaternion*, and we can also use 2×2 Pauli matrices in place of (i, j, k) if we want.

Key to Quaternion Intuition

Fundamental Intuition: We know

$$q_0 = \cos(\theta/2), \quad \vec{\mathbf{q}} = \hat{\mathbf{n}}\sin(\theta/2)$$

We also know that any coordinate frame M can be written as $M = R(\theta, \hat{\mathbf{n}})$.

Therefore

 $\vec{\mathbf{q}}$ points exactly along the axis we have to rotate around to go from identity I to M, and the length of $\vec{\mathbf{q}}$ tells us how much to rotate.

Summarize Quaternion Properties

• Unit four-vector. Take $q=(q_0,q_1,q_2,q_3)=(q_0,\vec{\mathbf{q}})$ to obey constraint $q\cdot q=1$.

Multiplication rule. The quaternion product q and p is

$$q*p=(q_0p_0-\vec{\mathbf{q}}\cdot\vec{\mathbf{p}},\ q_0\vec{\mathbf{p}}+p_0\vec{\mathbf{q}}+\vec{\mathbf{q}}\times\vec{\mathbf{p}}),$$
 or, alternatively,

$$\begin{bmatrix} [q*p]_0 \\ [q*p]_1 \\ [q*p]_2 \\ [q*p]_3 \end{bmatrix} = \begin{bmatrix} q_0p_0 - q_1p_1 - q_2p_2 - q_3p_3 \\ q_0p_1 + q_1p_0 + q_2p_3 - q_3p_2 \\ q_0p_2 + q_2p_0 + q_3p_1 - q_1p_3 \\ q_0p_3 + q_3p_0 + q_1p_2 - q_2p_1 \end{bmatrix}$$

Quaternion Summary . . .

• Rotation Correspondence. The unit quaternions q and -q correspond to a single 3D rotation R_3 :

$$\begin{bmatrix} q_0^2 + q_1^2 - q_2^2 - q_3^2 & 2q_1q_2 - 2q_0q_3 & 2q_1q_3 + 2q_0q_2 \\ 2q_1q_2 + 2q_0q_3 & q_0^2 - q_1^2 + q_2^2 - q_3^2 & 2q_2q_3 - 2q_0q_1 \\ 2q_1q_3 - 2q_0q_2 & 2q_2q_3 + 2q_0q_1 & q_0^2 - q_1^2 - q_2^2 + q_3^2 \end{bmatrix}$$

Quaternion Summary . . .

• Rotation Correspondence. Let

$$q = (\cos\frac{\theta}{2}, \hat{\mathbf{n}}\sin\frac{\theta}{2}),$$

with $\hat{\mathbf{n}}$ a unit 3-vector, $\hat{\mathbf{n}} \cdot \hat{\mathbf{n}} = 1$. Then $R(\theta, \hat{\mathbf{n}})$ is usual 3D rotation by θ in the plane \perp to $\hat{\mathbf{n}}$.

Inversion. Any 3 × 3 matrix R can be inverted for q up to a sign. Carefully treat singularities! Can choose sign, e.g., by local consistency, to get continuous frames.

SUMMARY

- Complex numbers represent 2D frames.
- Complex multiplication represents 2D rotation.
- Quaternions represent 3D frames.
- Quaternion multiplication represents 3D rotation.
